

I have a few more questions regarding the oil exploration in west Greenland.

- 1) Did the EIA study the effects of the drilling mud chemicals on zooplankton? What were the results?
- 2) In the case of a blowout will dispersants be used? If yes what type of dispersant? Have these dispersants been tested on zooplankton?
- 3) Are Clathrate Hydrates present?
- 4) What are the risks of drilling where Clathrate Hydrates are present?
- 5) Can gas hydrates stop a blowout preventer?

I look forward to your replies
